Forklift Drive Axles

Forklift Drive Axle - A forklift drive axle is actually a piece of equipment which is elastically fastened to a vehicle frame with a lift mast. The lift mast is attached to the drive axle and could be inclined around the drive axle's axial centerline. This is accomplished by at the very least one tilting cylinder. Frontward bearing components along with back bearing elements of a torque bearing system are responsible for fastening the vehicle and the drive axle framework. The drive axle could be pivoted around a swiveling axis oriented transversely and horizontally in the vicinity of the back bearing elements. The lift mast can also be inclined relative to the drive axle. The tilting cylinder is attached to the vehicle frame and the lift mast in an articulated fashion. This enables the tilting cylinder to be oriented almost parallel to a plane extending from the swiveling axis to the axial centerline.

Model H35, H40, and H45 forklifts, that are manufactured by Linde AG in Aschaffenburg, Germany, have a connected lift mast tilt on the vehicle frame itself. The drive axle is elastically affixed to the framework of the forklift utilizing numerous various bearings. The drive axle contains a tubular axle body together with extension arms affixed to it and extend rearwards. This type of drive axle is elastically attached to the vehicle frame by back bearing elements on the extension arms together with forward bearing devices located on the axle body. There are two back and two front bearing devices. Each one is separated in the transverse direction of the lift truck from the other bearing tool in its respective pair.

The drive and braking torques of the drive axle are sustained through the rear bearing elements on the frame using the extension arms. The load and the lift mast produce the forces that are transmitted into the road or floor by the frame of the vehicle through the drive axle's anterior bearing parts. It is essential to ensure the components of the drive axle are configured in a rigid enough manner in order to maintain strength of the forklift truck. The bearing components could reduce minor road surface irregularities or bumps through travel to a limited extent and give a bit smoother operation.
